Abstract

This study investigated the effects of royal jelly (RJ) on acetic acid-induced colitis in rats. Twenty adult female Wistar albino rats were divided into four treatment groups of 5 animals each, including a control group (Group I); Group II was treated orally with RJ (150 mg kg⁻¹ body weight); Group III had acetic acid-induced colitis; and Group IV had acetic acid-induced colitis treated orally with RJ (150 mg kg⁻¹ body weight) for 4 weeks. Colitis was induced by intracolonic instillation of 4% acetic acid; the control group received physiological saline (10 mL kg⁻¹). Colon samples were obtained under deep anaesthesia from animals in all groups. Tissues were fixed in 10% formalin neutral buffer solution for 24 h and embedded in paraffin. Six-micrometre-thick sections were stained with Mallory’s triple stain and toluidine blue in 1% aqueous solution at pH 1.0 for 5 min (for Mast Cells). RJ was shown to protect the colonic mucosa against the injurious effect of acetic acid. Colitis (colonic damage) was confirmed histomorphometrically as significant increases in the number of mast cells (MC) and colonic erosions in rats with acetic acid-induced colitis. The RJ treatment significantly decreased the number of MC and reduced the area of colonic erosion in the colon of RJ-treated rats compared with rats with untreated colitis. The results suggest that oral treatment with RJ could be used to treat colitis.

Introduction

The constant exposure of the intestinal epithelium to diverse types of nutrients and microorganisms present in the natural flora leads to permanent stress for enterocytes. Mucosal surfaces of the intestinal tract represent one of the main routes for microbial pathogens to enter a host and are important sites of microbially induced diseases. Natural compounds, such as components of green tea and RJ, can play a significant role against inflammation, cancer, cell proliferation and liver damage. RJ is a traditional product commonly used to supplement the medical treatment of various diseases. It is secreted from the hypopharyngeal and mandibular glands of young worker bees, to feed young larvae and the adult queen bee. RJ contains many important compounds with biological activity, such as free amino acids, proteins, sugars, fatty acids, minerals (e.g. iron and calcium) and vitamins (mainly thiamine, niacin, riboflavin). Several reports in the literature demonstrate the immunomodulatory properties of RJ.

The ability of MCs to release proinflammatory and immunoregulatory mediators has led to speculation that they are involved in gastrointestinal pathologies, such as intestinal allergy, coeliac disease and inflammatory bowel disease (IBD). In patients with IBD, the numbers of intestinal MC are increased. They have been shown to account for 60 and 30% of all mucosal cells immunoreactive for tumour necrosis factor (TNF)-α and interleukin (IL)-5, respectively. In previous studies, many authors identified changes in MCs in inflammatory bowel diseases, including ulcerative colitis. In addition, in vitro studies with MCs isolated from intestinal tissue demonstrated increased release of histamine and eicosanoids in MCs derived from patients with IBD compared with control patients. Such data support the hypothesis that MCs are primed or preactivated by the local inflammatory tissue environment.

Intracolonic application of acetic acid has long been used as an artificial method to induce colitis in experimental animals. Although it is known that the MC population in the intestine may be involved in pathologic changes in the colon, very few data are available on changes in the number and distribution of MCs in colon of subjects with colitis. These parameters were therefore investigated in this study, which also examined, for the first time, the effect of RJ on numerical distribution of MCs and on the ability of rat colonic mucosa tissue to generate after acetic acid-induced colitis. The aim of the present study was to evaluate the protective and antioxidative effect of RJ in acetic acid-induced colonic damage by determining changes in tissue histology and number of MCs.

Materials and Methods

Animals

Twenty adult female Wistar albino rats (n=5×4) weighing about 300 g were obtained from the Laboratory of Animal Science, Medical School, Firat University, Elazig, Turkey. The animals were given standard rat pellets (Van Feed Factory, Van, Turkey) and tap water ad libitum and were housed in individual cages (360×200×190 mm³), each containing 2 or 3 animals, from 7 days before the start of the experiment.

The rats were divided into four equal groups [Group I – control group, Group II – royal jelly-treated (RJ), Group III – acetic acid-treated (Colitis) and Group IV – acetic acid-treated (Colitis) + royal jelly (CRJ)]. Group I received normal food and water during the experiment. Group II received normal food and royal jelly (150 mg kg⁻¹) suspended in water. Group III received normal food and a dose of acetic acid dissolved in 0.9% NaCl delivered via the anus to the colon. Group IV received normal food along with 150 mg kg⁻¹ royal jelly and a per anum dose of acetic acid dissolved in 0.9% NaCl.

The RJ used was purchased from a local natural food store, Istanbul, Turkey. All animals were housed in stainless steel cages under standard laboratory conditions (light period 07.00 h to 20.00 h, 21±2°C, relative humidity 55%), and received humane care according to the criteria outlined in the Guide for the Care and Use of Laboratory Animals prepared by the National Academy of Sciences and published by the National Institute of Health.

Amino acid content of royal jelly

The amino acid content of the RJ used is given in Table 1. The main amino acids pres-
ent were lysine (62.4 mg 100 g⁻¹) and proline (58.76 mg 100 g⁻¹).

**Induction of experimental colitis**
All experimental animals were fasted for 24 h before induction of colitis. Each rat was lightly anaesthetised with ether, and a polyethylene cannula was inserted into the lumen of the colon via the anus. The tip of the cannula was positioned at 8 cm proximal to the anus. Either 1 mL of acetic acid (4% vol/vol in 0.9% NaCl) or saline as the inert control was slowly infused into the distal colon. After 30 seconds exposure, 1 mL of saline (0.9%) was instilled in order to withdraw the previous solution from the colon.

**Histological analysis**
One month after experiment beginning, rats were sacrificed under ether anaesthesia and the colon of each animal was excised and gently rinsed under tap water. The colon was then stretched on a piece of cork with mucosal surface upwards in the standard position for macroscopic examination and the severity of colitis was scored with the help of a magnifying glass. Finally, the colon was dissected and some crypts with focal ulceration. Microscopic examination of the colon mucosa showed lesions that varied in extent and depth (Figure 1 C).

**Statistical analyses**
The results are expressed as mean ± standard deviation. The Bonferroni multiple comparison procedure was then utilised for identifying differences among means. Differences were considered significant at P<0.05.

**Results**
Light microscopy examination of the colon mucosa of control rats (Group I) and RJ rats (Group II) stained with Mallory’s triple stain showed normal mucosal (crypts) glands with intact epithelial surfaces (Figure 1A, B). The surface epithelium and the crypt architecture were normal, comprising columnar epithelial and goblet cells. The rats with acetic acid-induced colitis (Group III) exhibited severe damage to the colon mucosa, with pathological changes including massive destruction of the epithelial layer and cellular debris, haemorrhagic colitis in the colon mucosa and gross lesions in the colon. The main histological finding was the presence of necrosis associated with haemorrhage. Histology revealed coagulative necrosis of the surface epithelium and some crypts with focal ulceration. Microscopic examination of the colon mucosa showed lesions that varied in extent and depth (Figure 1 C). Oral treatment with 150 mL kg⁻¹ RJ gave a protective effect against acetic acid-induced colitis in Group IV rats. The colon mucosa of these rats showed superficial ulceration and slight focal congestion and the crypts appeared normal. Mild cellular infiltration was apparent in the lamina propria and submucosa (Figure 1 D), while the protective effect was mild with 150 mg kg⁻¹ dose of RJ.

The numbers of MCs in the colon increased after acetic acid administration, but the number of colonic MCs in the colitis + RJ group (Group IV) was significantly lower than that in the colitis group. The histological appearance and distributions of numbers of MCs is summarized in Figures 2 and 3.
Discussion

This study demonstrates for the first time that RJ has beneficial effects on the colon of rats with acetic acid-induced colitis. Introduction of acetic acid into the colon lumen induced gross lesions in the mucosal part of the intestine and caused typical colitis damage, which was confirmed histomorphometrically by significant increases in diarrhea, congestion and swelling. Pronounced destructive changes associated with ulcerative colitis and haemorrhages were also observed in the colon of rats with acetic acid-induced colitis.

Treatment of colitic rats with an oral dose of RJ gave a degree of recovery from acute colitis. The anti-colitogenic effects of RJ could be attributed to improvement of the antioxidant status of the animals due to an increase in mucin content of the colon mucosa. Polyphenolic compounds in their many forms are the main components responsible for the functional properties associated with many foods, such as antioxidant capacity and anti-inflammatory capacity. RJ contains polyphenolic compounds collected by bees from the plants where they gather nectar.

Previous studies suggested that \textit{Nigella sativa} oil could protect the gastric mucosa against ethanol-induced ulcer. Kanbur et al. reported that RJ protects against liver damage induced by paracetamol. RJ has been shown to exhibit anti-inflammatory, DNA-protective, and anti-tumour effects in experimental animals. Hamerlink reported that RJ exhibited immunomodulatory properties by stimulating antibody production and immunocompetent cell proliferation in mice or by depressing humoral immune functions in rats. Another report indicated that the protection imparted by RJ ingestion could be partly attributed to the presence of neopterin in RJ. The protection afforded by RJ against the immunosuppression produced by increased PGE2 levels has been demonstrated in studies \textit{in vivo} and \textit{in vitro}.

El-Nekeety et al. found a potential protective effect of RJ against the toxic hazards of fumonisins. Kamakura et al. reported that RJ in the diet decreased the gene expression of cytokine P450 4A14 (CYP4A14) enzymes and detoxifying enzymes, which catalyse peroxidation of endogenous lipids, and increased the gene expression of glutathione S-transferase and glutathione peroxidase. Ethanol has been proven to cause gastric damage, an effect confirmed histomorphometrically by significant increases in the number of MC and gastric erosions. In the present study, acetic acid-induced colitis caused pronounced destructive changes associated with haemorrhage in the colon of affected rats, as well as increasing number of MC (Figure 2 C). The ulcerative erosions in colon tissues of rats with acetic acid-induced colitis decreased when the animals were treated with RJ (Figure 2 D). In addition, RJ prevented any increase in the number of MCs. Oral treatment with an aqueous solution of RJ (150 mL kg$^{-1}$) demonstrated a good level of colitis protection.

These findings are in good agreement with recent results presented by El-Dakhakhny et al. and Kanter et al., who found that \textit{Nigella sativa} had a gastroprotective action in an ethanol-induced ulceration model. Gebbers et al. observed an increase in the number of IgE positive plasma cells and the appearance of intraepithelial MCs in patients with rectal spirochaetosis. Morris et al. suggested that MCs numbers increased in inflamed tissues 3-4 weeks after colitis induction. In other studies, an increased MC count in the 5-20 day period and an elevated MC protease-2 (RMPC-2) level at 3 weeks were reported in colonic tissue taken from TNBS rats. Xu et al. reported that MC numbers in the colon of Sabra rats with TNBS-induced colitis were lower during the first five days after induction.

As a result, while acetic acid application caused damage to the colon mucosa of rats, treatment with RJ was found to diminish the harmful effects of acetic acid. Although it has been considered that it might exert the benefits through its antioxidant features, the exact mechanism of effect is yet unknown. In conclusion, it could be suggested that the efforts to focus on the effect mechanisms of RJ and other traditional medicinal supplements may provide new opportunities for the development of useful drugs.
