Abstract

As a metastasis suppressor, KiSS1 has been implicated in numerous human cancers. However, recent studies have demonstrated that KiSS1 promotes tumor growth and metastasis in breast cancer, and it is unclear about the expression and function of KiSS1 in human osteosarcoma (OS). The aim of the present study was to investigate the role and molecular mechanisms of KiSS1 in human OS. The expression of KiSS1 was assessed by immunohistochemical assay using a tissue microarray procedure in forty cases of OS tissues. A gain-of-function approach was used to observe the effects of lentiviral vector-mediated overexpression of KiSS1 (Lv-KiSS1) on the biological behaviors including proliferative activities and invasive potential of OS MG-63 cells, indicated by MTT and Transwell assays, respectively. The results showed that the expression of KiSS1 protein in OS tissues was significantly lowered compared to that in adjacent non-cancerous tissues (42.5% vs 70.0%, P=0.023), and had negative correlation with distant metastases of the tumor (P=0.019). Overexpression of KiSS1 inhibited proliferation and invasion of OS cells with the decreased expression of p38 MAPK and matrix metalloproteinase-9 (MMP-9). Taken together, our findings indicate that the decreased expression of KiSS1 is correlated with distant metastasis of OS, and KiSS1 may function as a tumor suppressor in OS cells through inhibition of the MAPK pathway, suggesting that KiSS1 may serve as a potential therapeutic target for the treatment of cancer.

Introduction

Osteosarcoma (OS) is the most common type of primary malignant bone tumor in children and adolescents and generally follows an aggressive clinical course.1 OS is a highly aggressive neoplasm that is resistant to current therapeutic approaches, including radiation, chemotherapy, and surgical treatment. Although 5-year survival rates of OS up to 50-70% can be achieved by using current treatment protocols, a substantial group of patients with metastatic, recurrent, and refractory disease remains without effective treatment options.2,3 Tumor is also a genetic disease, and develops in a multi-step process; single or multiple mutations in genes related to growth control and metastasis form the molecular genetic basis of malignant transformation and tumor progression. Therefore, identification of molecular targets that can be exploited in the clinic to treat metastatic disease is desperately needed.

The KiSS1 metastasis suppressor gene has emerged as a promising molecular target for the management of metastatic disease. KiSS1 has been intensively studied in physiology with diverse functions including the expression in the human and rat carotid body and superior cervical ganglion,4 but its role in cancer is still unclear. The whole genome microarray analysis identifies KiSS1 to be important in the progression and prognosis of metastatic cancers.5 Numerous clinical reports demonstrate that a loss or reduction of KiSS1 expression in different human cancers inversely correlates with tumor progression, metastasis, and survival.6,7 The diagnostic and prognostic utility of KiSS1 methylation also suggests its assessment for the clinical management of cancer patients.8,9 Moreover, KiSS1 mediates platinum sensitivity and metastasis suppression in head and neck squamous cell carcinoma10 and pancreatic adenocarcinoma,11 suggesting potential targets for therapy in cancer. However, some studies have shown that KiSS1 plays a role in promoting tumor development. KiSS1 expression is found to be increased and correlates with poor prognosis of hepatocellular carcinoma12 and estrogen receptor-positive breast tumors,13,14 suggesting an independent prognostic marker for tumor aggressiveness. To elucidate the function of KiSS1 in cancer, in the present study, the expression of KiSS1 in OS tissues was assessed by an immunohistochemical (IHC) assay using a tissue microarray procedure, and a gain-of-function approach was employed to investigate the effects of KiSS1 overexpression on the biological behaviors including proliferative activities and invasive potential of OS MG-63 cells, indicated by MTT and Transwell assays, respectively. We hypothesize that KiSS1 might serve as a potential therapeutic target for the treatment of cancer.

Materials and Methods

Materials

The OS MG-63 cell line used for experiments was obtained from the Institute of Biochemistry and Cell Biology (Shanghai, China). Lentivirus-mediated KiSS1 vector, negative control vector, and virion-packaging elements were purchased from Genechem (Shanghai, China); KiSS1 and p38 MAPK primers were synthesized by ABI (Framingham, MA, USA). The tissue microarray of human OS was purchased from the branch of Biomax (Xi’an, China). All antibodies were obtained from Santa Cruz Biotechnology (Dallas, TX, USA).

Drugs and reagents

Dulbecco’s Modified Eagle medium (DMEM) and fetal bovine serum (FBS) were purchased from Thermo Fisher Scientific Inc. (Waltham, MA, USA); TRizol Reagent and Lipofectamine 2000 were obtained from Invitrogen (Carlsbad, CA, USA); M-MLV Reverse Transcriptase was purchased from Promega (Madison, WI, USA); SYBR Green Master Mix was obtained from Takara (Otsu, Japan); and the ECL Plus Kit was obtained from GE Healthcare (Piscataway, NJ, USA).

Clinical samples and data

A tissue microarray was prepared for the IHC test using a total of 40 consecutive cases of human OS tissues and corresponding adjacent non-cancerous tissue (ANCT), which were collected from the Orthopedics Department of Shanghai Zhebei District Central Hospital from January 2007 to

Quantification of KiSS1 protein expression

KiSS1 expression was semiquantitatively estimated as the total KiSS1 immunostaining score, which was calculated as the product of a proportion score and an intensity score. The proportion score reflected the fraction of positively stained cells (score 0, <5%; score 1, 5%-10%; score 2, 10-49%; score 3, 50%-75%; score 4, >75%). The intensity score represented the staining intensity (score 0, no staining signal; score 1, weak positive signal; score 2, moderate positive signal; score 3, strong positive signal). Finally, a total expression score was given, ranging from 0 to 12. The score 0 was regarded as negative, score 1-3 was regarded as +, score 4-6 was regarded as ++, score 7-9 was regarded as ++++, and score 10-12 was regarded as +++++. Two observers estimated the total immunostaining score, independently and blindly. The total score reported was the average of two observers.

Cell culture and transfection

MG-63 cells were cultured in DMEM medium supplemented with 10% heat-inactivated FBS, 100 U/mL of penicillin, and 100 µg/mL of streptomycin. Cells in this medium were placed in a humidified atmosphere containing 5% CO2 at 37°C. Cells were subcultured at a 1:5 dilution in medium containing 300 µg/mL G418 (an aminoglycoside antibody, commonly used as stable transfection reagent in molecular genetic testing). On the day of transduction, MG-63 cells were replated at 5×10⁴ cells/well in 24-well plates containing serum-free growth medium with polybrene (5 µg/mL). When reached 50% confluence, cells were transfected with recombinant experimental virus or control virus at the optimal MOI (multiplicity of infection) of 50, and cultured at 37 and 5% CO2 for 4 h. Then supernatant was discarded and serum containing growth medium was added. At 4 days of post-transduction, transduction efficiency was measured by the frequency of green fluorescent protein (GFP)-positive cells. Positive and stable transfectants were selected and expanded for further study. The KiSS1 virus vector-infected clone, the negative control vector-infected cells, and MG-63 cells were named as Lv-KiSS1, NC, and CON groups, respectively.

Quantitative real-time PCR

To quantitatively determine the mRNA expression level of KiSS1 and p38MAPK in the MG-63 cell line, real-time PCR was performed. Total RNA was extracted from each clone using TRIzol according to the manufacturer’s protocol. Reverse transcription was carried out using M-MLV and cDNA amplification was performed using the SYBR Green Master Mix kit according to the manufacturer’s guidelines. The KiSS1 gene was amplified using a specific oligonucleotide primer and the human glyceraldehyde-3-phosphate dehydrogenase (GAPDH) gene was used as an endogenous control. Data were analyzed using the comparative Ct method (2^(-DDCt)). Three separate experiments were performed for each clone.

Western blot assay

MG-63 cells were harvested and extracted using lysis buffer (Tris-HCl, SDS, mercaptoethanol, and glycerol). Cell extracts were boiled for 5 min in loading buffer, and then an equal amount of cell extracts was separated on 15% SDS-PAGE gels. Separated protein bands were transferred onto polyvinylidene fluoride (PVDF) membranes, which were subsequently blocked in 5% skim milk powder. Primary antibodies against KiSS1, p38MAPK, and MMP-9 were diluted according to the manufacturer’s instructions and incubated overnight at 4°C. Subsequently, horseradish peroxidase-linked secondary antibodies were added at a dilution of 1:1000 and incubated at room temperature for 2 h. The membranes were washed 3 times with PBS, and the immunoreactive bands were visualized using the ECL Plus Kit according to the manufacturer’s instructions. The relative protein levels in different cell lines were normalized to the concentration of GAPDH. Three separate experiments were performed for each clone.

Cell proliferation assay

Cell proliferation was analyzed using the MTT assay. Briefly, cells infected with KiSS1 virus were incubated in 96-well-plates at a density of 1×10⁴ cells per well with DMEM medium supplemented with 10% FBS. Cells were treated with 20 µL of MTT dye at 0, 24, 48, 72, 96 h, and subsequently incubated with 150 µL of DMSO for 5 min. The color reaction was measured at 570 nm using an Enzyme Immunoassay Analyzer (Bio-Rad, Hercules, CA). The proliferation activity was calculated for each clone.

Transwell invasion assay

Transwell filters were coated with Matrigel (3.9 mg/mL; 60-80 µL on the upper surface of a polycarbonate membrane (diameter, 6.5 mm; pore size, 8 µm). After incubating at 37°C for 30 min, the Matrigel solidified and served as the extracellular matrix for analysis of tumor cell invasion. Harvested cells (1×10⁵) in 100 µL of serum-free DMEM were added into the upper compartment of the chamber. A total of 200 µL of conditioned medium derived from NIH3T3 cells was used as a source of chemoattractant, which was placed in the bottom com-
partment of the chamber. After 24 h of incubation at 37°C with 5% CO2, the medium was removed from the upper chamber. The non-invaded cells on the upper side of the chamber were scraped off with a cotton swab. Cells that had migrated from the Matrigel into the pores of the inserted filter were fixed with 100% methanol, stained with hematoxylin, then mounted and dried at 80°C for 30 min. The number of cells invading through the Matrigel was counted in 3 randomly selected visual fields from the central and peripheral portion of the filter by using an inverted microscope (200× magnification). Each assay was repeated 3 times.

Statistical analysis

The SPSS 20.0 software was used for statistical analyses. The Kruskal-Wallis H test, chi-square test, and one-way analysis of variance (ANOVA) were employed to analyze the expression rate in all groups. The LSD method of multiple comparisons was used when the probability for ANOVA was statistically significant. Significance was defined as P<0.05.

Results

The expression of KiSS1 in osteosarcoma tissues

The expression of KiSS1 protein was evaluated using IHC staining in OS tissues; as shown in Figure 1, different levels of positive expression of KiSS1 protein were examined in OS tissues. Positive KiSS1 immunostaining was localized in the nucleus and cytoplasm of OS tissue cells. According to the KiSS1 immunoreactive intensity, the positive expression of KiSS1 in OS tissues was significantly decreased compared with that of KiSS1 in ANCT (P=0.023) (Table 1).

Association between KiSS1 expression and clinicopathologic characteristics

The association of KiSS1 expression with various clinical and pathologic factors was analyzed. As shown in Table 2, KiSS1 expression was closely correlated with distant metastasis of OS (P=0.019). However, no significant correlation was found between KiSS1 expression and other factors including age, gender of the patients, and histology and Enneking staging of the tumor (P>0.05, separately).

The effect of KiSS1 overexpression on the expression of p38MAPK

After OS MG-63 cells were stably transfected with Lv-KiSS1, the mRNA and protein expression levels of KiSS1 and p38MAPK were detected by real-time PCR (Figure 2 A,B) and Western blot assays (Figure 2 C,D). The results showed that the expression of KiSS1 was remarkably increased, while that of p38MAPK was decreased in Lv-KiSS1 group compared to NC and CON groups (P<0.01, each).

The effect of KiSS1 overexpression on cell proliferation

Deregulated cell proliferation is a hallmark of cancer. To know about the effect of KiSS1 overexpression on tumor growth in OS MG-63 cells, we evaluated the proliferative activities of MG-63 cells by MTT assay. We found that KiSS1 overexpression markedly suppressed the proliferative activities of MG-63 cells in a time-dependent manner compared to NC and CON groups (Figure 3).

The effect of KiSS1 overexpression on cell invasion

To determine the effect of KiSS1 overexpression on the invasive potential of MG-63 cells, a Transwell assay was performed. The invasive potential of tumor cells in Transwell assay was determined by the ability of cells to invade a matrix barrier containing laminin and type IV collagen, the major components of the basement membrane. Representative micrographs of Transwell filters can be seen in Figure 4A. We found that the invasive potential of OS cells was apparently decreased in Lv-KiSS1 group compared to NC and CON groups (P<0.01) (Figure 4B). To understand the molecular mechanisms of KiSS1 on cell invasion, we examined the expression of MMP-9 in Lv-KiSS1-transfected OS cells by Western blot assay (Figure 4 C,D), and found that the expression level of MMP-9 was significantly reduced in Lv-KiSS1 group compared to NC and CON groups (P<0.01).

Discussion

KiSS1 has been originally identified as a metastasis-suppressor gene able to inhibit tumor progression. The expression of KiSS1 is found to be decreased in many tumors,17-19 and the loss of KiSS1 expression correlates with the progression of lymph node metastasis in human colorectal cancer,18 indicating the unfavorable prognosis for disease outcome.19 Some studies reveal that KiSS1 mRNA expression is also markedly reduced in tissues of breast cancer,20 while other ones show that KiSS1 is highly expressed in estrogen receptor (ER)-positive breast tumors compared to the ER-negative tumors.21 KiSS1 expression levels are found to be decreased in OS cell lines with increasing aggressiveness, while increases in human OS tissues and correlates with the metastasis of OS.22 Differently from the study of Wang et al.,22 we found in the present study that KiSS1 was proved to be decreased in the nucleus and cytoplasm of human OS tissues compared to the ANCT, suggesting that loss of KiSS1 expression might be involved in the development of OS.

Many studies have demonstrated that KiSS1, a key regulator of puberty, is discovered as a tumor metastasis suppressor. In addition to the reduced or lost expression of KiSS1 in different metastatic tumors, overexpression of KiSS1 inhibits growth and invasion of tumor cells through inhibition of RhoA-mediated NF-kB activation.23,24 However, individual study has indicated that new clones expressing KiSS1 show no decrease in metastatic growth, and metastasis suppressor KiSS1 lacks anti-
metastatic activity in melanoma.\textsuperscript{25} Nevertheless, our present study showed that overexpression of KiSS1 inhibited growth and invasion of OS cells with decreased expression of p38MAPK, suggesting that KiSS1 might function as a tumor suppressor in OS through regulation of the MAPK signaling.

Evidence indicates that elevated expression of interstitial collagenases including MMP-9 is associated with a poor prognosis in a variety of cancers and serves as a marker of tumor progression.\textsuperscript{26} KiSS1 expression is found lowered in hepatocellular carcinoma (HCC), and has a negative correlation with MMP-9 expression, suggesting a possible mechanism for cell motility and invasion during tumor metastasis.\textsuperscript{27} KiSS1, a metastasis suppressor gene, exerts its influence on invasion phenotype through inhibition of NF-κB signaling, which in turn regulates MMP-9 production facilitating invasion.\textsuperscript{28} KiSS1 suppresses MMP-9 expression by activating the p38 MAPK signaling pathway in stomach cancer.\textsuperscript{29} However, our present study indicated that KiSS1 inhibited the expression of p38 MAPK and MMP-9 and tumor growth and invasion in OS cells, while inhibition of p38 MAPK pathway decreases the expression of MMP-9 in OS cells,\textsuperscript{30} suggesting KiSS1 might have anti-tumor effect through inhibition of MAPK-mediated MMP-9 expression in OS cells.

In conclusion, our findings indicate that KiSS1 expression is downregulated in OS tissues, and KiSS1 may function as a tumor suppressor in OS cells through inhibition of MAPK pathway, suggesting that KiSS1 may serve as a potential therapeutic target for the treatment of cancer.
